What’s New?

Recent Important Publications and Research Trials
2011-2012
Daily Step Target to Measure Adherence to Physical Activity Guidelines in Children

RACHEL C. COLLEY\textsuperscript{1,2}, IAN JANSSSEN\textsuperscript{3}, and MARK S. TREMBLAY\textsuperscript{1,2}

\textsuperscript{1}Healthy Active Living and Obesity Research Group, Children’s Hospital of Eastern Ontario Research Institute, Ottawa, Ontario, CANADA; \textsuperscript{2}Faculty of Medicine, Department of Pediatrics, University of Ottawa; and \textsuperscript{3}School of Kinesiology and Health Studies, and Department of Community Health and Epidemiology, Queen’s University, Kingston, Ontario, CANADA

Goal: find step count for moderate – vigorous PA
N= 1613, 6-19 years; number of valid days = 9879

12,000 steps/day – a target to determine whether children 6-19 yr are meeting the current PA guidelines of 60 minutes of daily MVPA
30 minutes/day of MVPA: 7,900 steps/day for males
8,300 steps/day for females.

In a subsample of participants (n=1,197) we found 150 minutes/week of MVPA translated to ~ 7,000 steps/day (or 49,000 steps/week).

Accumulating ~ 8,000 steps/day is a good proxy for 30 minutes of daily MVPA, while accumulating 7,000 steps/day every day is consistent with obtaining 150 minutes of weekly MVPA.

Perilipin 1 is a protein that acts by preventing a "fat-burning" enzyme (HSL) from entering fat cells where it can break down fat molecules and convert them to energy. The protein plays an extremely significant role in whether fat is stored or released for use as energy.

The PLIN1 can determine one’s fat oxidation and fat weight loss response to exercise training.

Shepard S et al. Exp Physiol. 2012 April
Energy balance and its components: implications for body weight regulation

Kevin D. Hall\textsuperscript{4}, Steven B. Heymsfield\textsuperscript{5}, Joseph W. Kemnitz\textsuperscript{6}, Samuel Klein\textsuperscript{7}, Dale A. Schoeller\textsuperscript{8}, and John R. Speakman\textsuperscript{9}*

\textsuperscript{4}National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; \textsuperscript{5}Pennington Biomedical Research Center, Baton Rouge, LA; \textsuperscript{6}Institute for Clinical and Translational Research, University of Wisconsin, Madison, WI; \textsuperscript{7}Washington University School of Medicine, St Louis, MO; \textsuperscript{8}Nutritional Sciences, University of Wisconsin, Madison, WI; and \textsuperscript{9}Institute of Biological and Environmental Sciences, University of Aberdeen, Aberdeen, United Kingdom
1. A popular belief is that exercise training results in body composition changes that generate an additional energy benefit mediated through Resting Energy Expenditure (REE) Measurements that are not so confounded suggest that the impact of exercise training on REE is negligible.

2. The origin of the “3500 kcal per pound” rule is based on the calculated energy content of body weight change and is often misapplied to predict the weight-change time course after a given intervention. This is a fundamental error because no time period is specified for that intervention.
Effects of intensity and volume on insulin sensitivity during acute bouts of resistance training

17 adults with IFG completed 4 separate bouts of resistance exercise under moderate intensity (65% 1RMax) or high intensity (85% 1RM) conditions within the confines of single set and multiple set protocols.

High-intensity protocols resulted in greater insulin sensitivity (0.83 multiple set; 0.53 single set) as compared with moderate-intensity protocols. The high-intensity, multiple set bout yielded the greatest effect in both fasting glucose (0.61) and insulin sensitivity (0.83).
What’s new since Hippocrates? Preventing type 2 diabetes by physical exercise and diet

J. A. Hawley · M. J. Gibala

10 X 60 sec @ 90% HR_{max} (cycling)
Both resistance- and endurance-type exercise reduce the prevalence of hyperglycemia in individuals with impaired glucose tolerance and in insulin-treated and non-insulin-treated type 2 diabetic patients

van Dijk JW et.al. Diabetologia 2012;55:1273-82

15 pts with IGT and 15 pts with T2D

EndEx: 45 min cycling at 50% Wmax  
ResEx: 45 min of lat pulls, chest press, leg press and ext.
3-5 sets of 10 reps at 55-75% of 1RMax

A *single session* of EndEx or ResEx substantially reduces the prevalence of hyperglycemia and improves glycemic control during the subsequent 24 h period in individuals with IGT, and in insulin-treated and non-insulin-treated type 2 diabetic patients.
Impact of exercise intensity and duration on insulin sensitivity in women with T2D

METHODS: 22 women with T2D participated in a supervised group exercise program for 6 months. The program combined endurance and resistance exercise.

Improvement in insulin sensitivity after six months is related to exercise intensity,
The reduction in HbA1c is related mainly to training volume (total kcal expenditure).

Metabolic effects of training may be seen in the absence of improved exercise capacity.
Structured exercise training of more than 150 minutes per week is associated with greater HbA1c declines than that of 150 minutes or less per week.

Our results demonstrate that in patients with type 2 diabetes, structured aerobic, resistance, or combined exercise training is associated with a HbA1c decline of 0.67%.
So, what did we learn from these recent trials?

- Step target for MVPA for all kids: 12,000/day
- 8,000 steps/day is a good proxy for 30 min of MVPA for adults
- Genetic factors play a role (20-40%) in exercise-generated weight loss
- From a practical point of view the benefit of acute exercise on REE is negligible
- It appears that exercise intensity is more related to insulin sensitization whereas total exercise volume (total daily EE) is related to HbA1C
- Higher intensity exercise generates somewhat greater insulin sensitization than moderate intensity exercise – but it can be risky
- A single 45-min dose of exercise (AE or RT) can decrease hyperglycemia ~30-35% for 24 hours
- Structured exercise training ≥ 150 minutes/week is related to greater declines in HbA1C
Consensus Guidelines on PA

Risk reduction vs Weight loss
Public Health vs. Weight Loss Physical Activity Recommendations

Public Health:
150 minutes/week = 30 min/day x 5 days/wk

~1000 – 1,500 kcal/wk (20-30K+ steps/wk)

Weight Loss:
250-300 minutes/week = ≥60 min/day x 5 or more days/wk

~2,000 – 3,000 kcal/wk (40-60K+ +steps/wk)

Although physical activity (PA) is a key element in the prevention and management of type 2 diabetes, many with this chronic disease do not become or remain regularly active. High-quality studies establishing the importance of exercise and fitness in diabetes were lacking until recently, but it is now well established that participation in regular PA improves blood glucose control and can prevent or delay type 2 diabetes, along with positively affecting lipids, blood pressure, cardiovascular events, mortality, and quality of life. Structured interventions combining PA and modest weight loss have been shown to lower type 2 diabetes risk by up to 58% in high-risk populations. Most benefits of PA on diabetes management are realized through acute and chronic improvements in insulin action, accomplished with both aerobic and resistance training. The benefits of physical training are discussed, along with recommendations for varying activities, PA-associated blood glucose management, diabetes prevention, gestational diabetes mellitus, and safe and effective practices for PA with diabetes-related complications.

Diabetes Care 33:e147–e167, 2010

disease (CVD), blindness, kidney and nerve disease, and amputation (261). Although regular physical activity (PA) may prevent or delay diabetes and its complications (10,46,89,112,176,208,259,284), most people with type 2 diabetes are not active (193).

In this article, the broader term “physical activity” (defined as “bodily movement produced by the contraction of skeletal muscle that substantially increases energy expenditure”) is used interchangeably with “exercise,” which is defined as “a subset of PA done with the intention of developing physical fitness (i.e., cardiovascular [CV], strength, and flexibility training).” The intent is to recognize that many types of physical movement may have a positive effect on physical fitness, morbidity, and mortality.
Diet vs Exercise for Weight Loss

In randomized control trials, about 1 h of daily moderate aerobic exercise produces at least as much fat loss as equivalent caloric restriction, with resultant greater insulin action.

Ross 2000, 2004

ACSM/ADA 2011
Evidence statement

A combination of aerobic and resistance exercise training may be more effective in improving BG control than either alone;

however, more studies are needed to determine if total caloric expenditure, exercise duration, or exercise mode is responsible.
Supervision of training

Exercise intervention studies showing the greatest effect on blood glucose control have all involved supervision of exercise sessions by qualified exercise trainers.

The most direct test of the incremental benefits of supervised training was the Italian Diabetes and Exercise Study.
The optimal volume of exercise to achieve sustained major weight loss is probably much larger than the amount required to achieve improved blood glucose control and CV health.
Evidence statement

In addition to aerobic training, persons with type 2 diabetes should undertake moderate to vigorous resistance training at least 2–3 days/week.
Those prescribing exercise are required to understand that those with T2D for > 5-8 years tend to exhibit these exercise responses:

- **Chronotropic incompetence** (↓ heart rate)
- **Blunted systolic blood pressure response**
- **Attenuated V•O₂ kinetics** (aerobic capacity)
- **Anhydrosis** (inadequate sweat response)
  - Monitor the signs and symptoms of hypoglycemia
  - **Rating Perceived Exertion** should also be used to assess exercise intensity

PEDIATRIC DIABETES GUIDELINES
Aerobic, Muscle-strengthening, and Bone-strengthening Activities

Every day children and adolescents should do 1 hour or more of physical activity.

Aerobic activities. Most of the 1 hour a day should be either moderate or vigorous-intensity* aerobic physical activity, and include and include vigorous-intensity physical activity at least 3 days a week.

As a part of the 1 hour a day of physical activity, the following should be included:

- **Muscle-strengthening on at least 3 days a week.** These activities make muscles do more work than usual during daily life. They should involve a moderate to high level of effort and work the major muscle groups of the body: legs, hips, back, abdomen, chest, shoulders, and arms.

- **Bone-strengthening on at least 3 days of the week.** These activities produce a force on the bones that promotes bone growth and strength through impact with the ground.

Youth should be encouraged to engage in physical activities that are appropriate for their age, enjoyable, and offer variety.

No period of activity is too short to count toward the Guidelines.

Conflict of interest: PA has received unrestricted support of medical equipment (monitors and sensors) from Medtronic during studies on exercise. GS has sat on the CDE Advisory Panel for Unomedical and Medingo, has received speaker’s fees from Dexcom and Medtronic Diabetes, and has received writer’s fees from Becton Dickinson and Medtronic Diabetes. The remaining authors have no potential conflicts to declare.

This article is a chapter in the ISPAD Clinical Practice Consensus Guidelines 2009 Compendium. The complete set of guidelines can be found at www.ispad.org. The evidence grading system used in the ISPAD Guidelines is the same as that used by the American Diabetes Association. See page 2 (the Introduction in Pediatric Diabetes 2009; 10 (Suppl. 12): 1–2).
It is especially important to plan for long duration or intense aerobic exercise, or else hypoglycemia is almost inevitable. Nearly all forms of activity lasting > 30 minutes will be likely to require some adjustment to food and/or insulin.

Young people with T1D have been found to have decreased aerobic capacity as measured by VO2 max, compared to nondiabetic control subjects

ISPAD 2009
When regular (soluble) insulin has been injected prior to exercise, the most likely time for hypoglycemia will be 2-3h after injection and the high risk time after rapid-acting analog insulin is between 40 and 90 minutes.
Key Exercise Recommendations

Pediatric T1D

- Avoid exercise if BG < 100 or > 300 mg/dL
- Check ketones if BG > 250 and exercising
- Take 15 g of carbohydrates for every 30 min
- Check BG every 30-60 min during ex
- Avoid using legs for injections e.g., running (increased absorption) – abdomen better

<tr>
<td>Friday</td>
<td>20-min walk (or 5 x 4 min at work)</td>
</tr>
</tbody>
</table>

1 weekend day: 2hr+ drop-off *variable terrain walk-hike*

**TOTAL EE:** 400 + 1200 kcal = 1600+ kcal *

* Add 10-25% at BMI’s 35
Overweight and obese prediabetes and diabetes patients expend more calories for a given walking workout that those who are normal weight.
Thus, even walking may represent a difficult exercise modality for obese individuals because they can use:

- as much as 56% VO2max (some at BMI’s >40 using 64-98% VO2max) to meet the demand of such an activity compared with only 35% in normal-weight subjects.

56% vs 35%

Workplace EE

5 min/hr × 7 hrs

35 min @ 3-4 kcal/min

2000-2500 steps

100 – 140 kcal

(insulin sensitization – e.g., 10-15 mg metformin)

Exercise Program Screening

Why is this important?

- Regular exercise improves cardiometabolic health and reduces cardiovascular morbidity and mortality.
- Patients with or at high risk for CVD or diabetes have up to a ten-fold increase in cardiovascular events during exercise, compared to healthy persons.
- Patients with CVD should be identified by screening, evaluated and counseled before beginning a moderate to vigorous exercise program.

Action steps:

- Use one of the two screening instruments prior to recommending or starting an exercise program for your patients:
  - AHA/ACSM Health and Fitness Facility Preparticipation Screening Questionnaire
  - PDR Exercise Readiness Checklist

Systematic Clinical Pedometry

The application of the systematic use of well-engineered pedometers as objective activity outcomes measures in prediabetes and diabetes
Pediatric 7-Day Step Activity Assessment

**Youth Stepcount Activity Log**

**Name:**

**Instructions:**
- Wear the pedometer **tightly on your waist (beltline)** and directly over your **right leg**.
- **Reset your pedometer to ZERO** after each day.
- Record your total stepcount for **two full SCHOOL DAYS** (e.g., 7 a.m. to bedtime).
- Record your total stepcount for **two full WEEKEND DAYS** (e.g., 7 a.m. to bedtime).

*If you play sports include the pedometer stepcount **during that sport** (when the pedometer can be worn with your athletic gear)*

Return this log to the next Personal Fitness merit badge class.

Are there risk reduction differences?

1. An active lifestyle expending $\geq 1500$ kcal/week from a variety of domestic, recreational and work-related activities

2. An inactive work and recreational lifestyle but works out 3-5 days/week for 1500 kcal/week
Diverse types of moderate exercise is also associated with lower incidence of diabetes and CVD mortality.

This includes such utilitarian activities as walking, gardening, climbing, and household/yard chores. Those who expend 1000 - 1500 kcal per week in such utilitarian activities may require very little additional exercise to lower diabetes and CVD risk.
